ABSTRACT

The invention is directed to systems, methods and computer
program products for increasing the power efficiency of a
display. An exemplary system includes a transfective display
that is operable in either a transmissive mode or a reflective
mode, and an illumination source with one or more distinct
peaks in the illumination source's transmission spectrum,
wherein light from the illumination source is directed towards
the transfective display during the transmissive mode of
operation. For the transmissive mode of operation, the trans-
fective display's transmission spectrum is configured to sub-
stantially match the illumination source's transmission spec-
trum such that one or more narrow passbands in the
transfective display's transmission spectrum substantially
overlap with the one or more distinct peaks in the illumination
source's transmission spectrum. For the reflective mode of
operation, the transfective display's reflection spectrum is
substantially inversely related to the transfective display's
transmission spectrum.

HIGH POWER EFFICIENCY LCD

BACKGROUND

Transmissive displays provide enhanced performance in many areas compared to transreflective displays or purely reflective displays. A transmissive display is illuminated from the back by an illumination source/light source (e.g., a backlight), and is viewed from the opposite side (i.e., the "front"). This type of display may be used in applications requiring high luminance levels (e.g., computer displays, televisions, personal digital assistants (PDAs), mobile phones, etc.). Unfortunately, the illumination source used to illuminate a transmissive display usually consumes much more power than the display.

One solution to this problem is to make the display reflective or transreflective. A reflective display (e.g., often found in digital watches or calculators) is illuminated by external light reflected by a diffusing reflector located behind the display. Although the absence of an illumination source reduces power consumption in a reflective display, the contrast on such displays is typically poorer than on transmissive displays. A transreflective display works as either a transmissive display or a reflective display, depending on the ambient light. For example, a transreflective display operates in a reflective mode when external light levels are high, and in a transmissive mode in darker environments via a backlight. Unfortunately, transreflective displays are not as power efficient as transmissive displays in the transmissive mode, and are not as power efficient as reflective displays in the reflective mode. Therefore, what is needed is a method to make transreflective displays more power efficient.

BRIEF SUMMARY

Embodiments of the invention are directed to systems, methods and computer program products for increasing the power efficiency of a display. In some embodiments, an exemplary method includes providing an illumination source with one or more distinct peaks in the illumination source's transmission spectrum; providing a transreflective display that has a transmissive mode of operation and a reflective mode of operation; directing light from the illumination source towards the transreflective display during the transmissive mode of operation; configuring, for the transmissive mode of operation, the transreflective display's transmission spectrum to substantially match the illumination source's transmission spectrum such that one or more narrow passbands in the transreflective display's transmission spectrum substantially overlap with the one or more distinct peaks in the illumination source's transmission spectrum; and enabling light from an ambient light source to illuminate the transreflective display during a reflective mode of operation, wherein for the reflective mode of operation, the transreflective display's reflection spectrum is substantially inversely related to the transreflective display's transmission spectrum.

In some embodiments, the illumination source does not direct light towards the transreflective display during the reflective mode. In some embodiments, the display is a liquid crystal display. In some embodiments, the illumination source comprises one or more nano-LEDs or one or more narrow spectrum light sources. In some embodiments, the illumination source comprises one or more nano-wires/tubes or one or more Quantum dots. In some embodiments, the illumination source comprises one or more lasers.

In some embodiments, the transmission spectrum of the illumination source can be modified such that the one or more

distinct peaks in the illumination source's transmission spectrum can be shifted. In some embodiments, the directing step comprises directing, via one or more light tubes, light from the illumination source towards the transreflective display during the transmissive mode of operation. In some embodiments, the one or more light tubes are positioned under the transreflective display and wherein the one or more illumination source are positioned to the left or right side of the transreflective display.

In some embodiments, the transreflective display comprises a transreflective layer that is either integrated into the transreflective display or is a separate foil distinct from the transreflective display. In some embodiments, the illumination source provides red light, green light, and blue light such that the one or more distinct peaks in the illumination source's transmission spectrum correspond to peaks associated with the red light, the green light, and the blue light.

In some embodiments, the transreflective display includes a pixel array comprising one or more pixels, wherein each pixel comprises either no sub-pixels or comprises one or more sub-pixels associated with one or more colors. In some embodiments, the transreflective display is a field-sequential display that switches between displaying images associated with different colors, wherein an image associated with a particular color is displayed during a predetermined time interval. In some embodiments, the illumination source switches between emitting light associated with different colors such that the illumination source emits light associated with the particular color during the predetermined time interval. In some embodiments, the transreflective display does not reflect color during the reflective mode. In some embodiments, wherein the transreflective display further comprises a color filter such that color is reflected during the reflective mode.

In some embodiments, the illumination source comprises a first group of mini-illumination sources that is activated and a second group of mini-illumination sources that is deactivated such that a first part of an image presented on the transreflective display is darker compared to a second part of the image presented on the transreflective display.

In some embodiments, the directing step comprises directing, via a diffusor, light from the illumination source towards the transreflective display during the transmissive mode of operation, wherein the diffusor controls how the light from the illumination source is distributed onto the transreflective display.

In some embodiments, a system is provided for increasing power efficiency of a transreflective display. In some embodiments, the system comprises a transreflective display that is operable in either a transmissive mode or a reflective mode; and an illumination source with one or more distinct peaks in the illumination source's transmission spectrum, wherein light from the illumination source is directed towards the transreflective display during the transmissive mode of operation. For the transmissive mode of operation, the transreflective display's transmission spectrum is configured to substantially match the illumination source's transmission spectrum such that one or more narrow passbands in the transreflective display's transmission spectrum substantially overlap with the one or more distinct peaks in the illumination source's transmission spectrum. For the reflective mode of operation, the transreflective display's reflection spectrum is substantially inversely related to the transreflective display's transmission spectrum. Additionally, the system may be configured to perform the processes described the exemplary method above.

In some embodiments, a computer program product is provided for increasing power efficiency of a transreflective

3

display. In some embodiments, the computer program product comprises a non-transitory computer-readable medium comprising code configured to cause a computer to: configure properties of a transfective display, wherein the transfective display has a transmissive mode of operation and a reflective mode of operation; establish one or more distinct peaks for a transmission spectrum associated with an illumination source; initiate provision of light from the illumination source to the transfective display during the transmissive mode of operation; configure, for the transmissive mode of operation, the transfective display's transmission spectrum to substantially match the illumination source's transmission spectrum such that one or more narrow passbands in the transfective display's transmission spectrum substantially overlap with the one or more distinct peaks in the illumination source's transmission spectrum; and configure, for the reflective mode of operation, the transfective display's reflection spectrum such that the reflective spectrum is substantially inversely related to the transfective display's transmission spectrum. Additionally, the computer program product may be configured to perform the processes described the exemplary method above.

BRIEF DESCRIPTION OF THE DRAWINGS

Having thus described embodiments of the invention in general terms, reference will now be made to the accompanying drawings, where:

FIG. 1 is a block diagram illustrating an exemplary device that includes a display, in accordance with embodiments of the present invention;

FIG. 2 is a block diagram illustrating a partial side elevation view, in partial cross section, of the display of the device of FIG. 1, in accordance with embodiments of the present invention;

FIG. 3 is a block diagram illustrating a pixel of a pixel array illustrated in FIG. 2, in accordance with embodiments of the present invention;

FIG. 4 is a block diagram illustrating an embodiment of a system environment for increasing the power efficiency of a display, in accordance with embodiments of the present invention;

FIG. 5 is a block diagram illustrating another embodiment of a system environment for increasing the power efficiency of a display, in accordance with embodiments of the present invention;

FIG. 6 is a block diagram illustrating another embodiment of a system environment for increasing the power efficiency of a display, in accordance with embodiments of the present invention;

FIG. 7 is a block diagram illustrating another embodiment of a system environment for increasing the power efficiency of a display, in accordance with embodiments of the present invention; and

FIG. 8 is a flowchart illustrating a general process flow for increasing the power efficiency of a display, in accordance with embodiments of the present invention;

DETAILED DESCRIPTION OF EMBODIMENTS OF THE INVENTION

Embodiments of the present invention now may be described more fully hereinafter with reference to the accompanying drawings, in which some, but not all, embodiments of the invention are shown. Indeed, the invention may be embodied in many different forms and should not be construed as limited to the embodiments set forth herein; rather,

4

these embodiments are provided so that this disclosure may satisfy applicable legal requirements. Like numbers refer to like elements throughout.

Embodiments of the invention are directed to systems, methods and computer program products for increasing the power efficiency of a transfective display. As used herein, a transfective display comprises a translector or a transfective layer. In some embodiments, this transfective layer is integrated into the display. In other embodiments, the transfective layer may be provided as a foil distinct from the display. In embodiments of the invention, the properties of the transfective layer are configured or optimized based at least partially on spectral properties of the illumination source that provides light to the display and/or the transfective layer. As explained previously, a transfective layer may have two modes of operation: a transmissive mode and a reflective mode.

As used herein, power efficiency in the transmissive mode is the ratio of the amount of power actually used to illuminate the transfective display in the transmissive mode to the amount of power provided by the illumination source. As used herein, power efficiency in the reflective mode is the ratio of the amount of power actually used to illuminate the transfective display in the reflective mode to the amount of power associated with the amount of ambient light power as determined by a light sensor associated with the transfective display.

In some conventional transfective displays, the transmissive mode is associated with a higher power efficiency when compared to the reflective mode. This is because the construction or configuration of the transfective display is such that the transmissive mode is given higher priority when compared to the reflective mode. This means that the transfective display is designed for increasing power efficiency associated with receiving emitted light from an illumination source and illuminating the transfective display using the emitted light from the illumination source. This also means that the transfective display is not designed for increasing power efficiency associated with receiving ambient light and illuminating the display using the received ambient light.

In other conventional transfective displays, the reflective mode is associated with a higher power efficiency when compared to the transmissive mode. This is because the construction or configuration of the transfective display is such that the reflective mode is given higher priority when compared to the transmissive mode. This means that the transfective display is not designed for increasing power efficiency associated with receiving emitted light from an illumination source and illuminating the transfective display using the emitted light. Instead, this means that the transfective display is designed for increasing power efficiency associated with receiving ambient light and illuminating the display using the received ambient light.

Therefore, for the purposes of increasing the power efficiency of a transfective display, there is an inherent conflict between the transmissive mode and the reflective mode. The present invention resolves this conflict by providing methods, systems, and computer program products to simultaneously increase power efficiency of a transfective display for both the transmissive mode and reflective mode.

As used herein, a device may include a radiotelephone; a personal communications system (PCS) terminal that may combine a cellular radiotelephone with data processing, a facsimile, and data communications capabilities; a personal digital assistant (PDA) that can include a radiotelephone, pager, Internet/intranet access, web browser, organizer, calendar, a Doppler receiver, and/or global positioning system

5

(GPS) receiver; a laptop; a GPS device; a personal computer; an MP3 player; a printer; a facsimile machine; a pager; a calculator; a camera (e.g., digital or video); and/or any other device capable of utilizing a display.

FIG. 1 is a diagram of an exemplary device 100 according to an implementation of the present invention described herein. As shown in FIG. 1, device 100 may include a housing 110, a speaker 120, a display 130, control buttons 140, a keypad 150, a microphone 160, and/or a camera 170. Housing 110 may protect the components of device 100 from outside elements. Speaker 120 may provide audible information to a user of device 100. Display 130 may provide visual information to the user. For example, display 130 may provide information regarding incoming or outgoing calls, games, phone books, the current time, emails, etc. Control buttons 140 may permit the user to interact with device 100 to cause device 100 to perform one or more operations. Keypad 150 may include a standard telephone keypad and/or may include additional keys to enable typing information into device 100. Microphone 160 may receive audible information from the user. Camera 170 may enable a user to capture and/or store video and/or images (e.g., pictures).

Embodiments of the invention are not limited methods, systems, and computer program products associated with mobile device displays. Embodiments of the invention are applicable to any display, e.g., a television display, a computer display, etc.

FIG. 2 is a partial side elevation view, in partial cross section, of display 130. As shown in FIG. 2, display 130 may include an illumination source 200, a pixel array 210, a transmissive layer 230, etc. In some embodiments, the transmissive layer 230 may be comprised within the pixel array 210, while in other embodiments, the transmissive layer 230 may be provided separately from the pixel array 210. Display 130 may include other components (e.g., electrical components, optical components, etc.) not shown in FIG. 2.

The illumination source 200 may include any device capable of providing illumination or lighting to display 130 and/or pixel array 210 and/or transmissive layer 230. As used herein, an illumination source 200 may also be referred to as an illumination device, a backlight source, or a backlight device. For example, illumination source 200 may include an incandescent light bulb, one or more light-emitting diodes (LEDs), an electroluminescent panel (ELP), one or more cold cathode fluorescent lamps (CCFL), one or more hot cathode fluorescent lamps (HCFL), etc. An incandescent light bulb may be used when very high brightness is desired. LEDs may be used in small, inexpensive displays, and may include colored or white light. An ELP may be used for larger displays or when even lighting is desired, and may be either colored or white. CCFLs may be used on large displays (e.g., computer monitors) and may be white in color. In another example, illumination source 200 may employ a diffuser or light guide to provide even lighting from an uneven source. In still another example, illumination source 200 can include any color light source (e.g., yellow, green, blue, white, etc.) or any combination of colored/non-colored light sources.

In some embodiments, light may be directly provided from the illumination source 200 to the transmissive layer 230. In such embodiments, the illumination source 200 may be positioned adjacent to and/or under the transmissive layer 230. However, in other embodiments, a light guide may be provided to guide light from the illumination source 200 to the transmissive layer 230. In such embodiments, the illumination source 200 need not be positioned adjacent to and/or under the transmissive layer 230. In such embodiments, the illumination source 200 may be positioned to right or left side

6

of the transmissive layer 230 and a light guide may be used to direct light to the transmissive layer 230. In such embodiments, the light guide may be positioned under (or behind) the transmissive layer 230. The light guide may receive light from the illumination source 200 that is positioned to the right or left side of the transmissive layer 230, and may reflect the received light towards the transmissive layer 230.

Pixel array 210 may include any device capable of providing visual information (e.g., text, images, video, incoming or outgoing calls, games, phone books, the current time, emails, etc.) to a user. For example, pixel array 210 may include a liquid crystal display (LCD), such as a thin film transistor (TFT) LCD display, or a high performance addressing (HPA) LCD display.

In one implementation of the present invention, pixel array 210 may include any number of color and/or monochrome pixels arrayed in front of a light source (e.g., illumination source 200). In another implementation, pixel array 210 may include electrodes on one side of pixel array 210 that may be grouped and wired together with gate or column lines, and each group may receive its own voltage source. Pixel array 210 may further include electrodes on another side of pixel array 210 that may be grouped and wired together with row lines, and each group may receive its own voltage sink. The groups may be designated so that each pixel of pixel array 210 may have a unique combination of source and sink.

In still another implementation of the present invention, pixel array 210 may include a passive-matrix structure or an active-matrix structure. In a passive-matrix structure, each row or column of pixel array 210 may include a single electrical circuit, and the pixels may be addressable one at a time by row and column addresses. Pixels may maintain their states between refreshes without the benefit of an electrical charge. In an active-matrix structure, a matrix of TFTs may be added to the polarizing and color filters, and each pixel may include its own dedicated TFT that allows each gate or column line to access one pixel. If a row line is activated, the gate lines may be connected to a row of pixels and a correct voltage may be driven onto all of the gate lines. The row line may be deactivated, and the next row line may be activated. All row lines may be activated in sequence during a refresh operation.

In a further implementation of the present invention, if pixel array 210 is a color array, each pixel may be divided into three cells, or subpixels, which may be colored red, green, and blue by additional filters (e.g., pigment filters, dye filters, metal oxide filters, etc.). Each subpixel may be controlled independently to yield thousands or millions of possible colors for each pixel. In other implementations, each pixel of pixel array 210 may include more or less than three subpixels of various colors other than red, green, and blue. In still other implementations, each pixel of pixel array 210 includes a single monochromatic subpixel. In embodiments of the invention, each pixel (and each subpixel associated with each pixel) of pixel array 210 can be configured or adapted to pass light of wavelengths transmitted from the illumination source 200.

In embodiments where the pixel array performs the function of the transmissive layer, each pixel or subpixel may include a transmissive section and a reflective section that permits the pixel or subpixel to work as either a transmissive display or a reflective pixel, respectively. For example, the pixel or subpixel may work reflectively when illumination source 200 is de-energized or turned off, and may work transmissively when illumination source 200 is energized or turned on.

FIG. 3 is a partial side elevation view of an exemplary pixel 400 of pixel array 210 of FIG. 2. Although FIG. 3 shows a

color pixel **400**, in other implementations, exemplary pixel **400** may include monochrome pixels. As shown, pixel **400** may include a red subpixel **415**, a green subpixel **435**, and a blue subpixel **455**, which may be associated with a row line **405** and gate lines **410**. As explained previously, in other

embodiments, pixel **400** may include a single monochromatic subpixel. As further shown in FIG. 3, red subpixel **415** may be associated with a reflective section **420**, a transmissive section **425**, and a TFT **430**. Ambient light may be reflected by reflective section **420** in the standby mode. Reflective section **420** may use a color filter (e.g., red) to create color. Ambient light may pass through reflective section **420** and through the color filter, may be reflected by reflective section **420** (and pass through the color filter again), and may be viewed as red subpixel **415**. Transmissive section **425** may include any material that may be illuminated from the back (e.g., with illumination source **200**), and is viewed from the opposite side (i.e., the front). Transmissive section **425** may also use the color filter (e.g., red) to create color. Light from illumination source **200** may be transmitted through transmissive section **425** and the color filter, and may be viewed as red subpixel **415**. TFT **430** may be electrically coupled to row line **405** and to a corresponding one of gate lines **410**. TFT **430** may permit row line **405** and/or the corresponding one of gate lines **410** to access red subpixel **415**.

Green subpixel **435** may be associated with a reflective section **440**, a transmissive section **445**, and a TFT **450**. Ambient light may be reflected by reflective section **440** in the standby mode. Reflective section **440** may use a color filter (e.g., green) to create color. Ambient light may pass through reflective section **440** and through the color filter, may be reflected by reflective section **440** (and pass through the color filter again), and may be viewed as green subpixel **435**. Transmissive section **445** may include any material that may be illuminated from the back (e.g., with illumination source **200**), and is viewed from the opposite side (i.e., the front). Transmissive section **445** may also use the color filter (e.g., green) to create color. Light from illumination source **200** may be transmitted through transmissive section **445** and the color filter, and may be viewed as green subpixel **435**. TFT **450** may be electrically coupled to row line **405** and to a corresponding one of gate lines **410**. TFT **450** may permit row line **405** and/or the corresponding one of gate lines **410** to access green subpixel **435**.

As further shown in FIG. 3, blue subpixel **455** may be associated with a reflective section **460**, a transmissive section **465**, and a TFT **470**. Ambient light may be reflected by reflective section **460** in the standby mode. Reflective section **460** may use a color filter (e.g., blue) to create color. Ambient light may pass through reflective section **460** and through the color filter, may be reflected by reflective section **460** (and pass through the color filter again), and may be viewed as blue subpixel **455**. Transmissive section **465** may include any material that may be illuminated from the back (e.g., with illumination source **200**), and is viewed from the opposite side (i.e., the front). Transmissive section **465** may also use the color filter (e.g., blue) to create color. Light from illumination source **200** may be transmitted through transmissive section **465** and the color filter, and may be viewed as blue subpixel **455**. TFT **470** may be electrically coupled to row line **405** and to a corresponding one of gate lines **410**. TFT **470** may permit row line **405** and/or the corresponding one of gate lines **410** to access blue subpixel **455**.

Referring now to FIG. 4, an exemplary system environment **401** is provided for increasing the power efficiency of a display **130**, in accordance with embodiments of the present

invention. The pixel array **210** provided in the display **130** can be based on any of the previously described pixel array configurations, e.g., pixels with monochromatic subpixels, pixels with color subpixels (e.g., red, green, blue subpixels, etc.), pixels with no sub-pixels, etc. The transmissive layer **230** has been described previously. The sun **260** is a representation of the ambient light source. Additionally, the display **130** includes a light sensor that is not shown in FIG. 4. The illumination source **200** has been described previously. In some embodiments, the illumination source **200** is part of the display **130**, while in other embodiments, the illumination source **200** is separate from the display **130**. As shown in FIG. 4, the illumination source **200** emits RGB (red, green, and blue) light. However, embodiments of the invention are not limited to any particular type (or wavelengths) of light emitted by the illumination source **200**.

In some embodiments, the red light, the green light, and the blue light are emitted simultaneously by the illumination source **200**. However, in other embodiments, each of the red light, the green light, and the blue light are emitted by the illumination source **200** during separate distinct time intervals. Therefore, in such embodiments, when the red light is emitted during a particular time interval, neither the green light nor the blue light is emitted during that particular time interval. Similarly, when the green light is emitted during a particular time interval, neither the red light nor the blue light is emitted during that particular time interval. Similarly, when the blue light is emitted during a particular time interval, neither the green light nor the red light is emitted during that particular time interval. In some embodiments, there might be an idle non-zero time interval between the emitting of each type of light.

Embodiments of the invention are directed to any illumination source for which one or more narrow bands of wavelengths of light can be selected for emission from the illumination source **200**, i.e., a user may configure (e.g., via a user interface associated with the system) the illumination source **200** to emit light associated with one or more distinct narrow bands of wavelengths. For example, in some embodiments, the illumination source **200** may be configured to emit a light associated with a single distinct wavelength or a very narrow band of wavelengths. As explained further below, in some embodiments, in response to the user's configuration of the illumination source **200**, the transmission spectrum of the transmissive layer **230** of the display **130** may automatically configure itself such that the narrow passbands of the transmission spectrum of the transmissive layer **230** automatically overlap with the newly configured peaks of the of illumination source's transmission spectrum.

The illumination source **200** is not limited to any specific technology. In some embodiments, the illumination source **200** may include one or more narrow spectrum light sources, such as one or more nano-LEDs. In some embodiments, the illumination source **200** may include one or more lasers. In some embodiments, the illumination source **200** uses nano-based technology. For example, the illumination source **200** may include one or more Quantum dots. As a further example, the illumination source **200** comprises one or more nano-wire LEDs which have a selectable dominant wavelength (e.g., selectable via a user interface associated with the system) and a stable transmission spectrum. As explained with the illumination source **200** described previously, the nano-wire LEDs may be placed behind or under the LCD display **130** (e.g., blue phase LCD display). In still other embodiments, the illumination source **200** may include a combination of the various types of illumination sources described herein.

In some embodiments, the illumination source **200** is a linear system, which means that the light is directly guided straight from the illumination source **200** to the display **130** (or the transfective layer **230**). In other embodiments, the illumination source **200** may be a non-linear system, which means that the light is not guided straight from the illumination source **200** to the display **130**, instead, the light may be guided to the display **130** via one or more light guides, which may be located under or behind the display **130**.

Embodiments of the invention are directed to configuring the properties of the transfective layer **230** such that the transmission spectrum **492** of the transfective layer **230** substantially matches the actual spectrum **491** of the illumination source **200**. As explained previously, in some embodiments, the transfective layer **230** may be part of the pixel array **210**. In some embodiments, a user of the system may configure the properties (e.g., the transmission spectrum **492**) of the transfective layer **230** via a user interface associated with the system. In some embodiments, a passband of the transmission spectrum **492** of the transfective layer **230** may be slightly broader than the width of a crest associated with light emitted from the illumination source **200**. In other embodiments, a passband of the transmission spectrum **492** of the transfective layer **230** may be slightly narrower than the width of a crest associated with light emitted from the illumination source **200**. The width of a crest may be the width at the bottom of the crest, the width in the middle of the crest, the width close to the top or at the top of the crest, etc.

This matching of the spectrums of the illumination source **200** and the transfective layer **230** enables increase in power efficiency during both the transmissive mode and the reflective mode for the transfective layer **230**. The graph on the right side of FIG. **4** is the graph for the transmissive mode of the transfective layer **230**. The x-axis of this graph represents the wavelengths of light. The y-axis of the graph in FIG. **4** and all other graphs described herein represents the intensity of light. As indicated by this graph, the transfective layer **230** is configured to allow light associated with red, green, and blue wavelengths to pass through the transfective layer **230**. By allowing light associated with wavelengths of the illumination source **200** to pass through the transfective layer **230** during the transmissive mode, the transfective layer **230** enables more light emitted from the illumination source **200** to illuminate information presented on the display **130**, thereby increasing the power efficiency during the transmissive mode. Additionally, by matching the spectrums of the illumination source **200** and the transfective layer **230**, less light received from the illumination source **200** is blocked by the transfective layer **230**.

The graph on the left side of FIG. **4** is the graph for the reflective mode of the transfective layer **230**. As indicated by this graph, the transfective layer **230** is configured to block light associated with wavelengths of light emitted from the illumination source **200** (i.e., red, green, blue wavelengths). Also as indicated by this graph, in the reflective mode, the transfective layer **230** is configured **494** to pass light associated with wavelengths other than red, green, and blue wavelengths. By allowing light associated with wavelengths other than wavelengths of the illumination source **200** to be reflected **261** by the transfective layer **230** during the reflective mode, the transfective layer **230** enables more light **493** from the ambient light source **260** to illuminate information presented on the display **130**, thereby increasing the power efficiency during the reflective mode. Additionally, by matching the spectrums of the illumination source **200** and the transfective layer **230**, less light received from the ambient light source **260** is blocked by the transfective layer **230**. In

some embodiments, the spectrum **494** for the reflective mode may need to be separately configured, while in other embodiments, configuring the transmission spectrum **492** of the transfective layer **230** automatically results in the reflection spectrum **494** being configured for the reflective mode.

Therefore, when narrow band RGB (red green blue) light is used for the illumination source **200** and the transfective layer's transmission spectrum **492** is configured to allow the RGB light to pass through the transfective layer **230** during the transmissive mode, high levels of transmission and low levels of transmission loss, can be achieved during the transmissive mode. When the transfective layer's reflection spectrum **494** is configured allow light other than RGB light to pass through the transfective layer **230** during the reflective mode, high reflectance or reflectivity and low levels of reflection loss, can be achieved during the reflective mode. Therefore, the transfective layer **230** is transmissive only for the wavelengths emitted from the RGB LEDs, thereby achieving greater reflectivity without losing much transmissivity in the transmissive mode.

Referring now to FIG. **5**, another exemplary system environment **500** is provided for increasing the power efficiency of a display **130**, in accordance with embodiments of the present invention. The above description with respect to FIG. **4** also applies to FIG. **5**. In the embodiment presented in FIG. **5**, the display **130** is a field-sequential display. As used herein, a field-sequential display is a system in which color images (e.g., primary color images) are transmitted as a continuous stream of successive images, such that a human eye (or other imaging system) combines the continuous stream of color images into a unified color image. Therefore, the display **130** in FIG. **5** is a fast-switching display that supports field sequential colors. The field sequential colors are not limited to the primary colors (red, green, blue) described herein and may refer to any other color in the visible spectrum (e.g., violet, indigo, yellow, orange, or a combination of any number of colors in the visible spectrum). As indicated in FIG. **5**, in one embodiment, RGB light from the illumination source **200** switches in phase with the field sequential display **130**. Therefore, for example, when red light is emitted by the illumination source **200** during a particular time interval, the transfective layer **230** associated with the display **130** is configured to match its transmission spectrum **492** to the red light emitted by the illumination source **200** such that the transmissivity of red light through the transfective layer **230** is high. Similarly, the transmission spectrum **492** of the transfective layer **230** is configured to substantially block all wavelengths of light that are not red light during the same particular time interval. Therefore, when the illumination source **200** switches from emitting red light to emitting blue light, a transfective layer **230** also switches from a transmission spectrum **492** that passes red light to a transmission spectrum **492** that passes blue light. In some embodiments, a user of the system may configure or control the switching intervals for each of the colors of light emitted from the illumination source **200**. For example, a user may configure the system via a user interface of the system such that each color of light (e.g., red, green, and blue) are associated with equal emission time intervals. As a further example, a user may configure the system such that one color of light has a greater emission time interval compared to another color of light.

For the display **130** presented in FIG. **5**, each pixel of the pixel array **210** does not need to include a red subpixel, a green subpixel, and a blue subpixel, and instead may just include one or more monochromatic subpixels. When each pixel does not include RGB subpixels and includes only one

11

or more monochromatic subpixels or when each pixel does not include sub-pixels, at all, the display **130** cannot reflect color in the reflective mode. In alternate embodiments, each pixel of the pixel array **210** may include one or more subpixels, where each subpixel is associated with a different color (e.g., red subpixel, green subpixel, blue subpixel). In the embodiment presented in FIG. **5**, the illumination source **200** may use nano-based technology as described previously in order to increase power efficiency in both the transmissive and reflective modes.

Referring now to FIG. **6**, another exemplary system environment **600** is provided for increasing the power efficiency of a display **130**, in accordance with embodiments of the present invention. The above description with respect to FIG. **4** also applies to FIG. **6**. Additionally, the above description with respect to FIG. **5** may apply to FIG. **6**. In some embodiments, the display **130** presented in FIG. **6** is a field-sequential display, while in other embodiments, the display **130** presented in FIG. **6** is not a field-sequential display. The configuration of the system presented in FIG. **6** may not affect color presented in the transmissive mode. In the embodiment presented in FIG. **6**, the display **130** uses a color filter to achieve color in the reflective mode. The color filter may be a separate foil that is used along with the display **130**, or the color filter may be integrated into the display **130**. In some embodiments, the color filter may be configured such only particular colors (e.g., red and blue) are displayed in the reflective mode. In some embodiments, a user of the system may customize properties (e.g., wavelengths of light that passes through the color filter, wavelengths of light that are blocked by the color filter, etc.) of the color filter using an interface associated with the system. In some embodiments of the system presented in FIG. **5**, the illumination source **200** is not configured to continuously switch or scan red light, green light, and blue light. In other embodiments of the system presented in FIG. **5**, the illumination source **200** may be configured to continuously switch or can red light, green light, and blue light, similar to the embodiment presented in FIG. **5**. As with FIG. **5**, pixels comprised within the pixel array **210** located in the display **130** may comprise one or more monochromatic subpixels, or may comprise one or more subpixels, where each subpixel is associated with a different color (e.g., red subpixel, green subpixel, blue subpixel).

Additionally, as with the embodiments in FIGS. **4** and **5**, high transmissivity is achieved in the transmissive mode, and high reflectance is achieved in the reflective mode. In some embodiments a light sensor associated with the display **130** is configured to measure the ambient light. A processor associated with the system is then configured to compare the measured ambient light with a predetermined threshold amount. In some embodiments, the display **130** is configured to display color in the reflective mode when the ambient light is greater than or equal to a predetermined threshold amount, and is not configured to display color in the reflective mode when the ambient light is not greater than a predetermined threshold amount. In some embodiments, a user may be able to modify this predetermined threshold amount via a user interface associated with the system.

Referring now to FIG. **7**, another exemplary system environment **700** is provided for increasing the power efficiency of a display **130**, in accordance with embodiments of the present invention. The above description with respect to FIG. **4** also applies to FIG. **7**. Additionally, the above description with respect to FIGS. **5** and **6** may apply to FIG. **7**. In the embodiment presented in FIG. **7**, local dimming is combined with a transmissive layer **230** as described in FIGS. **4**, **5**, and **6**. The illumination source **200** presented in FIG. **7** may

12

comprise a large number of smaller illumination sources (may be based on nano technology as described earlier) placed adjacent to the display **130**. In some embodiments, each of these illumination sources can work independently from the other illumination sources. In other embodiments, each illumination source is part of a group of illumination sources that works independently from other groups of illumination sources, while illumination sources in each group work together (i.e., they are activated and deactivated together). In some embodiments, these illumination sources may be placed under the display **130**. In other embodiments, these illumination sources need not be placed under the display **130** (e.g., the illumination sources may be placed to the right or left side of a display), and one or more light guides, which may be placed under or behind the display **130**, may be used to direct light from the illumination source **200** towards the display **130**. In still other embodiments, one group of illumination sources may be placed under the display **130**, while other groups of illumination sources may be placed on the left or right side of the display **130**.

Using a large number of illumination sources enables local dimming or area dimming because some of the illumination sources that direct light to a particular area of the display **130** may be activated while other illumination sources that direct light to a different area of the display **130** may be deactivated. This allows selective dimming of the display **130** which enables power conservation and increase in contrast ratios. Therefore, using the configuration of the system in FIG. **7**, a part of the image presented on the display **130** may be dark, while another part of the image presented on the display **130** may be bright. In some embodiments, the amount of dimming associated with an illumination source **200** may be controlled as well. Therefore, a user may control or configure (e.g., via a user interface associated with the system) the number of illumination sources that are activated and/or deactivated and which illumination sources are activated and/or deactivated. In this way, a user may configure which area of the display **130** is bright and which area of the display **130** is dark. Additionally, the user may configure the intensity of brightness (or darkness) associated with bright (or dark) areas by controlling the number of illumination sources that are activated (or deactivated) or by controlling the diffusor's properties (as described below).

In some embodiments, power efficiency in both the transmissive and reflective modes may be obtained when the illumination sources are nano-wire LEDs (e.g., with configurable or customizable transmission spectrums) as described previously. In some embodiments, a user of the system may configure how each of the illumination sources is activated or deactivated as a function of time using a user interface associated with the system.

FIG. **7** also presents a diffusor (or a diffusing optics system) that is positioned adjacent to the display **130**. In the embodiment presented in FIG. **7**, the diffusor is positioned under the display **130** and is positioned over or on top of the illumination source **200**, which as described previously may comprise numerous smaller illumination sources. Light from the illumination source **200** (or from light tubes that receive light from the illumination source **200**) reaches the transmissive layer via the diffusor. In some embodiments, the diffusor is separate from the display **130** and separate from the illumination source **200**, which comprises a plurality of smaller illumination sources as described previously. In other embodiments, the diffusor may be integrated either into the display **130** or into the illumination source **200**. The diffusor reduces hotspots or uneven light distribution by controlling the distribution of light from the illumination sources on to

13

the display **130** or on to the transfective layer **230** of the display **130**. In some embodiments, a user of the system may configure properties (e.g., how light received from the illumination sources is distributed to the display **130**) of the diffusor via a user interface associated with the system. The properties may not only include how the light from the illumination sources is spread or distributed onto the display **130** (some areas may receive more light than others), but also how the light from the illumination sources is distributed or spread onto the display **130** as a function of time.

LED technologies, such as Quantum dots and nanotubes, are well suited to support both local dimming as described herein with respect to FIG. 7 and a transfective layer **230** as described in FIGS. 4, 5, 6, and 7. Therefore, embodiments of the invention are directed to combining nano-technology based LEDs (e.g., chromatic LEDs such as RGB LEDs or LEDs associated with any other color or combination of colors) with an illumination source with local dimming, and configuring or adapting a transfective layer of an LCD display (which may even be a fast-switching LCD display) based on the spectrum of the LEDs in order to obtain a power efficient LCD display.

In some embodiments, a user interface as described herein may be presented on the display presented in the Figures. In other embodiments, a user interface as described herein may be presented on a separate display different from the display presented in the Figures.

Referring now to FIG. 8, a general process flow **800** is provided for increasing the power efficiency of a display, in accordance with embodiments of the present invention. At block **810**, an illumination source is provided with one or more distinct peaks in the transmission spectrum (e.g., peaks for red, green, and blue light). In some embodiments, a user of the system may be allowed to configure the transmission spectrum of the illumination source by selecting one or more peaks. At block **820**, the transmission spectrum of a transfective layer associated with a display is configured to substantially match the illumination source's transmission spectrum for the transmissive mode of the transfective layer. In some embodiments, a user may be allowed to configure the transmission spectrum of the transfective layer for the transmissive mode. By allowing light associated with wavelengths of the illumination source to pass through the transfective layer during the transmissive mode, the transfective layer enables more light emitted from the illumination source to illuminate information presented on the display, thereby increasing the power efficiency during the transmissive mode.

At block **830**, for the reflective mode, the transmission spectrum of a transfective layer associated with a display is configured to substantially be the inverse of the transfective layer's transmission spectrum for the transmissive mode. In some embodiments, a user may be allowed to configure the transmission spectrum of the transfective layer for the reflective mode. In alternate embodiments, for the reflective mode, the transmission spectrum of the transfective layer is inversely related to or is configured to substantially be the inverse of the illumination source's transmission spectrum. By allowing light associated with wavelengths other than wavelengths of the illumination source to be reflected by the transfective layer during the reflective mode, the transfective layer enables more light from the ambient light source to illuminate information presented on the display, thereby increasing the power efficiency during the reflective mode. In some embodiments, when the transfective layer changes from the transmissive mode to the reflective mode (e.g., when ambient light intensity falls below a predetermined thresh-

14

old), the transfective layer changes from using the transmission spectrum to using the reflection spectrum in order to filter ambient light.

In some embodiments, a transfective layer switches from the reflective mode to the transmissive mode (or maintains the transmissive mode) when a processor associated with the display receives an ambient light level measured by a light sensor associated with the display, compares the ambient light level with a predetermined threshold, and determines that the ambient light level is less than the predetermined threshold. In such embodiments, when the transmissive mode is initiated, the illumination source is activated and directs light towards the transfective layer resulting in the display being illuminated by light received from the illumination source.

In some embodiments, a transfective layer switches from the transmissive mode to the reflective mode (or maintains the reflective mode) when a processor associated with the display receives an ambient light level measured by a light sensor associated with the display, compares the ambient light level with a predetermined threshold, and determines that the ambient light level is greater than or equal to the predetermined threshold. In such embodiments, when the reflective mode is initiated, the illumination source is deactivated and the display is illuminated only with light received from the ambient light source.

In accordance with embodiments of the invention, the term "module" with respect to a system (or a device) may refer to a hardware component of the system, a software component of the system, or a component of the system that includes both hardware and software. As used herein, a module may include one or more modules, where each module may reside in separate pieces of hardware or software.

Although many embodiments of the present invention have just been described above, the present invention may be embodied in many different forms and should not be construed as limited to the embodiments set forth herein; rather, these embodiments are provided so that this disclosure will satisfy applicable legal requirements. Also, it will be understood that, where possible, any of the advantages, features, functions, devices, and/or operational aspects of any of the embodiments of the present invention described and/or contemplated herein may be included in any of the other embodiments of the present invention described and/or contemplated herein, and/or vice versa. In addition, where possible, any terms expressed in the singular form herein are meant to also include the plural form and/or vice versa, unless explicitly stated otherwise. Accordingly, the terms "a" and/or "an" shall mean "one or more," even though the phrase "one or more" is also used herein. Like numbers refer to like elements throughout.

As will be appreciated by one of ordinary skill in the art in view of this disclosure, the present invention may include and/or be embodied as an apparatus (including, for example, a system, machine, device, computer program product, and/or the like), as a method (including, for example, a business method, computer-implemented process, and/or the like), or as any combination of the foregoing. Accordingly, embodiments of the present invention may take the form of an entirely business method embodiment, an entirely software embodiment (including firmware, resident software, micro-code, stored procedures in a database, etc.), an entirely hardware embodiment, or an embodiment combining business method, software, and hardware aspects that may generally be referred to herein as a "system." Furthermore, embodiments of the present invention may take the form of a computer program product that includes a computer-readable

15

storage medium having one or more computer-executable program code portions stored therein. As used herein, a processor, which may include one or more processors, may be “configured to” perform a certain function in a variety of ways, including, for example, by having one or more general-purpose circuits perform the function by executing one or more computer-executable program code portions embodied in a computer-readable medium, and/or by having one or more application-specific circuits perform the function.

It will be understood that any suitable computer-readable medium may be utilized. The computer-readable medium may include, but is not limited to, a non-transitory computer-readable medium, such as a tangible electronic, magnetic, optical, electromagnetic, infrared, and/or semiconductor system, device, and/or other apparatus. For example, in some embodiments, the non-transitory computer-readable medium includes a tangible medium such as a portable computer diskette, a hard disk, a random access memory (RAM), a read-only memory (ROM), an erasable programmable read-only memory (EPROM or Flash memory), a compact disc read-only memory (CD-ROM), and/or some other tangible optical and/or magnetic storage device. In other embodiments of the present invention, however, the computer-readable medium may be transitory, such as, for example, a propagation signal including computer-executable program code portions embodied therein.

One or more computer-executable program code portions for carrying out operations of the present invention may include object-oriented, scripted, and/or unscripted programming languages, such as, for example, Java, Perl, Smalltalk, C++, SAS, SQL, Python, Objective C, JavaScript, and/or the like. In some embodiments, the one or more computer-executable program code portions for carrying out operations of embodiments of the present invention are written in conventional procedural programming languages, such as the “C” programming languages and/or similar programming languages. The computer program code may alternatively or additionally be written in one or more multi-paradigm programming languages, such as, for example, F#.

Some embodiments of the present invention are described herein with reference to flowchart illustrations and/or block diagrams of apparatus and/or methods. It will be understood that each block included in the flowchart illustrations and/or block diagrams, and/or combinations of blocks included in the flowchart illustrations and/or block diagrams, may be implemented by one or more computer-executable program code portions. These one or more computer-executable program code portions may be provided to a processor of a general purpose computer, special purpose computer, and/or some other programmable data processing apparatus in order to produce a particular machine, such that the one or more computer-executable program code portions, which execute via the processor of the computer and/or other programmable data processing apparatus, create mechanisms for implementing the steps and/or functions represented by the flowchart(s) and/or block diagram block(s).

The one or more computer-executable program code portions may be stored in a transitory and/or non-transitory computer-readable medium (e.g., a memory, etc.) that can direct, instruct, and/or cause a computer and/or other programmable data processing apparatus to function in a particular manner, such that the computer-executable program code portions stored in the computer-readable medium produce an article of manufacture including instruction mechanisms which implement the steps and/or functions specified in the flowchart(s) and/or block diagram block(s).

16

The one or more computer-executable program code portions may also be loaded onto a computer and/or other programmable data processing apparatus to cause a series of operational steps to be performed on the computer and/or other programmable apparatus. In some embodiments, this produces a computer-implemented process such that the one or more computer-executable program code portions which execute on the computer and/or other programmable apparatus provide operational steps to implement the steps specified in the flowchart(s) and/or the functions specified in the block diagram block(s). Alternatively, computer-implemented steps may be combined with, and/or replaced with, operator- and/or human-implemented steps in order to carry out an embodiment of the present invention.

While certain exemplary embodiments have been described and shown in the accompanying drawings, it is to be understood that such embodiments are merely illustrative of and not restrictive on the broad invention, and that this invention not be limited to the specific constructions and arrangements shown and described, since various other changes, combinations, omissions, modifications and substitutions, in addition to those set forth in the above paragraphs, are possible. Those skilled in the art will appreciate that various adaptations, modifications, and combinations of the just described embodiments can be configured without departing from the scope and spirit of the invention. Therefore, it is to be understood that, within the scope of the appended claims, the invention may be practiced other than as specifically described herein.

What is claimed is:

1. A method for increasing power efficiency of a transmissive display, the method comprising:

providing an illumination source with at least one distinct peak in the illumination source’s transmission spectrum;

providing a transmissive display that has a transmissive mode of operation and a reflective mode of operation;

receiving user configuration of the illumination source, wherein the user configuration results in directing light from the illumination source towards the transmissive display during the transmissive mode of operation;

in response to the user configuration of the illumination source, automatically configuring, by a computer processor, for the transmissive mode of operation, the transmissive display’s transmission spectrum to substantially match the illumination source’s transmission spectrum such that at least one narrow passband in the transmissive display’s transmission spectrum substantially overlaps with the at least one distinct peak in the illumination source’s transmission spectrum; and

enabling light from an ambient light source to illuminate the transmissive display during a reflective mode of operation, wherein for the reflective mode of operation, the transmissive display’s reflection spectrum is substantially inversely related to the transmissive display’s transmission spectrum.

2. The method of claim 1, wherein the illumination source does not direct light towards the transmissive display during the reflective mode.

3. The method of claim 1, wherein the display is a liquid crystal display.

4. The method of claim 1, wherein the illumination source comprises at least one nano-LED or at least one other narrow spectrum light source.

5. The method of claim 1, wherein the illumination source comprises at least one nano-wires/tube or at least one Quantum dot.

17

6. The method of claim 1, wherein the illumination source comprises at least one laser.

7. The method of claim 1, wherein receiving the user configuration of the illumination source further comprises receiving the user configuration of the illumination source that modifies the transmission spectrum of the illumination source such that the at least one distinct peak in the illumination source's transmission spectrum is shifted.

8. The method of claim 1, wherein receiving the user configuration further comprises:

receiving the user configuration of the illumination source, wherein the user configuration results in directing, via at least one light tube, light from the illumination source towards the transfective display during the transmissive mode of operation.

9. The method of claim 8, wherein the at least one light tube is positioned under the transfective display and wherein the illumination source is positioned to the left or right side of the transfective display.

10. The method of claim 1, wherein the transfective display comprises a transfective layer that is either integrated into the transfective display or is a separate foil distinct from the transfective display.

11. The method of claim 1, wherein the illumination source provides red light, green light, and blue light such that the at least one distinct peak in the illumination source's transmission spectrum corresponds to peaks associated with the red light, the green light, and the blue light.

12. The method of claim 1, wherein the transfective display includes a pixel array comprising at least one pixel, wherein each pixel comprises either no sub-pixels or comprises at least one sub-pixel associated with at least one color.

13. The method of claim 1, wherein the transfective display is a field-sequential display that switches between displaying images associated with different colors, wherein an image associated with a particular color is displayed during a predetermined time interval.

14. The method claim 13, wherein the illumination source switches between emitting light associated with different colors such that the illumination source emits light associated with the particular color during the predetermined time interval.

15. The method of claim 1, wherein the transfective display does not reflect color during the reflective mode.

16. The method claim 1, wherein the transfective display further comprises a color filter such that color is reflected during the reflective mode.

17. The method of claim 1, wherein the illumination source comprises a first group of mini-illumination sources that is activated and a second group of mini-illumination sources that is deactivated such that a first part of an image presented on the transfective display is darker compared to a second part of the image presented on the transfective display.

18. The method of claim 1, wherein receiving the user configuration further comprises:

receiving the user configuration of the illumination source, wherein the user configuration results in directing, via a

18

diffusor, light from the illumination source towards the transfective display during the transmissive mode of operation, wherein the diffusor controls how the light from the illumination source is distributed onto the transfective display.

19. A system for increasing power efficiency of a transfective display, the system comprising:

a transfective display that is operable in either a transmissive mode or a reflective mode; and

an illumination source with at least one distinct peak in the illumination source's transmission spectrum, wherein the system is configured to provide for user configuration of the illumination source, such that the user configuration results in directing light from the illumination source towards the transfective display during the transmissive mode of operation,

wherein, in response to the user configuration of the illumination source, for the transmissive mode of operation, the transfective display's transmission spectrum is automatically configured to substantially match the illumination source's transmission spectrum such that at least one narrow passband in the transfective display's transmission spectrum substantially overlaps with the at least one distinct peak in the illumination source's transmission spectrum, and

wherein, for the reflective mode of operation, the transfective display's reflection spectrum is substantially inversely related to the transfective display's transmission spectrum.

20. A computer program product for increasing power efficiency of a transfective display, the computer program product comprising:

a non-transitory computer-readable medium comprising code configured to cause a computer to:

receive user configurations that (1) configure properties of a transfective display, wherein the transfective display has a transmissive mode of operation and a reflective mode of operation and (2) establish at least one distinct peak for a transmission spectrum associated with an illumination source;

initiate provision of light from the illumination source to the transfective display during the transmissive mode of operation;

in response to receiving the user configurations automatically configure, for the transmissive mode of operation, the transfective display's transmission spectrum to substantially match the illumination source's transmission spectrum such that at least one narrow passband in the transfective display's transmission spectrum substantially overlaps with the at least one distinct peak in the illumination source's transmission spectrum; and

configure, for the reflective mode of operation, the transfective display's reflection spectrum such that the reflective spectrum is substantially inversely related to the transfective display's transmission spectrum.

* * * * *
